2	Surveillance Summary
3	CENTRE FOR ENTERIC DISEASES
3	Laboratory-Based Enteric Disease Surveillance
4	<i>Salmonella</i> Typhi
5	<i>Vibrio cholerae</i> O1
6	Syndromic Diarrhoeal Disease Surveillance
6	Rotavirus (ROTA)
8	CENTRE FOR HIV AND STI
8	Sexually Transmitted Infections Surveillance
9	CENTRE FOR OPPORTUNISTIC, TROPICAL AND HOSPITAL INFECTIONS
9	Laboratory-Based Screening for Cryptococcal Disease
13	Laboratory-Based Nosocomial Disease Surveillance
13	<i>Staphylococcus aureus</i>
16	<i>Enterococcus, Staphylococcus, Klebsiella, Acinetobacter, Pseudomonas</i>, ESBL (ESKAPE)
20	Syndromic Respiratory Disease Surveillance
20	<i>Pneumocystis jirovecii</i>
22	CENTRE FOR RESPIRATORY DISEASES AND MENINGITIS
22	Laboratory-Based Respiratory and Meningeal Disease Surveillance
23	<i>Neisseria meningitidis</i>
24	<i>Haemophilus influenzae</i>
25	<i>Streptococcus pneumoniae</i>
26	Syndromic Respiratory Disease Surveillance
27	Influenza-like illness Primary Health Care clinics
28	Influenza-like illness (ILI) (Viral Watch)
29	Severe Acute Respiratory Illness (SARI)
31	Private hospital respiratory consultations
32	CENTRE FOR VACCINES AND IMMUNOLOGY
32	Case-based Measles Surveillance
35	Polio/ Acute Flaccid Paralysis (AFP) Surveillance

This Surveillance Report is published by the National Institute for Communicable Diseases (NICD), a division of the National Health Laboratory Service (NHLS), on a monthly basis to provide information on communicable diseases in South Africa. Much of the information is therefore preliminary and should not be cited or utilised for publication. Questions and comments may be addressed to the Division of Public Health Surveillance and Response and will be referred on to the responsible Centres: pennyc@nicd.ac.za; Private Bag X4, Sandringham, 2131, South Africa

Surveillance Summary

- *Salmonella* Typhi has been reported for 97 cases to date in 2014.
- Two cases of *Vibrio cholerae* O1 have been reported to date in 2014 in Gauteng province - serotype Ogawa, biotype El Tor. For the same period last year, 1 case had been reported in Limpopo province - serotype Inaba.
- Two hundred and eighteen specimens (n=935, 23%) have tested positive for rotavirus to date.
- Laboratory-based screening for cryptococcal disease has been operational in the City of Johannesburg Metro for almost 2 years and in the City of Ekurhuleni Metro for over a year. To date, 18544 patients have been screened at selected facilities; 839 (4.5%) tested positive for cryptococcal antigenaemia (CrAg).
- To 31 December 2014, 1228 *S. aureus* cases were reported over a 28 month period. The majority of cases were <10 years old (35%). The proportion of methicillin-resistant isolates were 32%.
- A total of 3917 patients over a 26 month period were tested for *Pneumocystis jirovecii*. Five hundred and forty-five (14%) cases were positive for *P. jirovecii*. These cases positive for *P. jirovecii* could indicate colonization or it could be true disease.
- The meningococcal season has ended with very few cases reported over the last few weeks. By week 52 in 2014, 188 meningococcal cases had been reported to the NICD. Serogrouping results to date include 39 B, 18 C, 55 W, 1 X and 28 Y. Most of the cases occurred in children aged <10 years.
- By week 52 in 2014, 288 cases of *H. influenzae* had been reported. Serotypes identified to date include 16 a, 49 b, 2 c, 4 d, 3 e, 8 f and 102 non-typeable. Most cases occur in individuals aged <10 years.
- The number of pneumococcal cases was lower than that reported last year (2539 versus 2866). Most cases occur in children aged <5 years and adults aged 30-34 years.
- To date in 2014, 881 influenza isolates have been detected. Five hundred and fifteen of the isolates were detected through Viral Watch, 75 through SARI and 291 through the influenza-like illness programme.
- Seventy-two measles cases were detected; 23 measles cases in Gauteng province, 6 cases in KwaZulu-Natal province, 30 cases in Northern Cape province, 5 cases in Western Cape province, 3 cases in Mpumalanga, 2 cases each in Free State and Eastern Cape provinces, and 1 in North West province. A measles outbreak was declared in ZF Mgcawu district in Northern Cape province.
- 399 AFP cases <15 years of age have been reported to date with an annualized non-polio AFP detection rate of 2.6 per 100,000 population.

Laboratory-Based Enteric Disease Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

The Centre for Enteric Diseases (CED) at the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) monitors disease caused by *Salmonella* Typhi and *Vibrio cholerae* through a national, active, laboratory-based surveillance system (as part of GERMS-SA). All microbiology diagnostic laboratories throughout South Africa are requested to report laboratory-confirmed disease (defined as the isolation of *Salmonella* Typhi and *Vibrio cholerae* from any specimen. Reporting laboratories should include all private- and public-sector health care laboratories, and other specialist laboratories e.g. laboratories serving mining or military hospitals. Available isolates are sent to CED for confirmation and further characterisation, including serotyping.

Some of the limitations of this surveillance system are that we include only individuals that arrive at hospitals and have specimens taken, and cases are only counted if laboratories report them to us. Quarterly audits to verify completeness of reporting are conducted for all public-sector laboratories. Frequent communications and visits are conducted to improve case reporting. Isolates for serotyping are not available for cases identified by audit.

Comments:

By week 52 in 2014, *Salmonella* Typhi had been reported for 97 cases (84 invasive), in Eastern Cape, Free State, Gauteng, KwaZulu Natal, Limpopo, Mpumalanga and Western Cape provinces. For the same period last year, 64 cases of *Salmonella* Typhi had been reported.

Two cases of *Vibrio cholerae* O1 has been reported to date in 2014 in Gauteng province - serotype Ogawa, biotype El Tor. For the same period last year, 1 case had been reported in Limpopo province - serotype Inaba.

Syndromic Diarrhoeal Disease Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

In April 2009, the National Institute for Communicable Diseases of the National Health Laboratory Services (NICD/ NHLS) implemented a diarrhoeal sentinel surveillance programme in six hospitals in five provinces (Gauteng, Gauteng/ North West border, Kwa-Zulu Natal, Mpumalanga and Western Cape). The aim of the programme is to evaluate the prevalence of rotavirus in diarrhoea cases and to monitor the effect of the introduction of the monovalent Rotarix® vaccine into the expanded programme on immunisation. The rotavirus vaccine was introduced in August 2009.

Children < 5 years admitted (slept overnight in hospital) to one of the sentinel hospitals for acute diarrhoea (≥ 3 loose stools in 24 hour period and onset within 7 days) are eligible for enrolment in the surveillance. Stool specimens are collected and tested for rotavirus at the NICD/NHLS and at the Diarrhoeal Pathogens Research Unit (DPRU), University of Limpopo, Medunsa Campus using the ProSpecT Rotavirus ELISA kit (Oxoid, UK).

Comments:

The start of the rotavirus season is defined as rotavirus detection rate of > 20% for two consecutive weeks and the end as rotavirus detection rate <20% for two consecutive weeks. The rotavirus season began in week 16 (14 April) and ended in week 34 (24 August). The maximum detection rate (65%; 30/44) for the 2014 rotavirus season was in week 27 (30 June), correlating with an increased submission of stool samples.

In 2013, the rotavirus season started in week 19 (week ending 12 May) and ended in week 40 (week ending 6 October), three weeks longer than the 2014 season.

For the period 6 January to 28 December 2014, 935 patients were tested for rotavirus. A total of 23% (218/935) were positive for rotavirus.

Syndromic Diarrhoeal Disease Surveillance

Rotavirus (ROTA) surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Figure 7. Number of stools tested for rotavirus and detection by week, 2014

The rotavirus detection (in percentage) is the number of rotavirus-positive stool tests divided by the number of rotavirus stool tests in acute diarrhoea hospitalisations.

Table 1. Cumulative number of stools tested rotavirus positive and total number of stools collected by hospital, 2014

Site	Rotavirus Positive	Total stools tested

Edendale	23	56
Red Cross Children's	51	285
Kimberley	2	28
Total:	218	935

Sexually Transmitted Disease Surveillance

Reporting period 01/04/2014 to 30/11/2014

Results until end of epidemiologic week 48 (2014)

Programme Description:

The Gauteng clinical STI sentinel surveillance programme was introduced in 1997 by the Sexually Transmitted Infections Reference Centre (Centre for HIV and STI, National Institute for Communicable Diseases) in partnership with the Gauteng Department of Health. The aim of the surveillance program is to monitor STI trends and set up priorities for STI management and provincial control programmes. The data presented below are a summary for the period 1 November - 30 November 2014.

Comments:

For the period 1-30 November 2014, 1,731 new STI syndrome episodes were reported by sentinel sites.

Females represented 39% (n=679) and males 61% (n=1,052) of the surveyed population. Amongst males, 52% (550/ 1,052) of STI syndromes were MUS (Male Urethritis Syndrome) and amongst females, 75% (511/ 679) of STI syndromes were VDS (Vaginal Discharge Syndrome). A total of 1,084 partner notification slips were issued to 1,731 patients with new STI episodes, resulting in an overall partner slip issue rate of 100%.

MUS and VDS continued to be the most common syndromes in this patient population group.

Figure 8. Percentage distribution of new STI syndrome episodes per surveillance region, 1–30 November 2014

Laboratory-Based Screening for Cryptococcal Disease (Phase 1: Gauteng)

Reporting period 03/09/2012 to 25/08/2014

Results until end of epidemiologic week 34 (2014)

Programme Description:

The NICD's Centre for Opportunistic, Tropical and Hospital Infections (COTHI), in collaboration with the Department of Health and several partner organizations, implemented the first phase of laboratory-based screening for cryptococcal disease. The screen-and-treat programme began at 21 health care facilities in the City of Johannesburg in September 2012. In April 2013, 85 facilities in Ekurhuleni were also included. Routine blood samples submitted for a CD4+ T-lymphocyte (CD4) count from patients seen at these 106 facilities are reflexively tested for cryptococcal antigen (CrAg) using a cryptococcal lateral flow assay (LFA) if the CD4 count is less than 100 cells/ μ l. CrAg test results are included on the CD4 count laboratory report. As part of intensive monitoring and evaluation of the programme, patients with cryptococcal antigenaemia, who provide informed consent, are followed up prospectively for up to 6 months. The following data are collected: lumbar puncture results; antifungal treatment; antiretroviral treatment; time from CrAg testing to treatment initiation; adverse events and outcome (i.e. development of cryptococcal meningitis (CM), death or loss to follow-up). Other key programme indicators such as number of cases of CM detected at the regional hospitals in the screening districts, the number of healthcare workers trained and availability of fluconazole at facilities are collected. The objective of this report is to provide monthly updates of selected programme indicators to all stakeholders. Data in this report are incomplete due to retrospective collection of clinical data.

Comments:

Up to 25 August 2014, 18,544 patients with a CD4 count <100 cells/ μ l have been screened; 839 (4.5%) tested positive for CrAg. In Johannesburg, 55% (208/377) of cases were detected at Helen Joseph Hospital and in Ekurhuleni, 14% (68/476) of cases were detected at Tambo Memorial Hospital. Twenty two per cent (177/812) of CrAg-positive patients with available age data were between the age of 30 and 44 years. During the reporting period, 337 cases of laboratory-confirmed CM were diagnosed at three regional hospitals (Helen Joseph, Rahima Moosa Mother and Child and South Rand) in Johannesburg and 412 cases of CM were diagnosed at four regional hospitals in Ekurhuleni (Bertha Gxowa, Natalspruit, Pholosong and Tambo Memorial); this number may include hospitalised patients who were not screened through this programme.

NB. Numbers in reporting may have changed relative to the previous quarterly report (May 2014) due to data source changes aimed at improving statistical accuracy

Laboratory-Based Screening for Cryptococcal Disease (Phase 1: Gauteng)

Reporting period 03/09/2012 to 25/08/2014

Results until end of epidemiologic week 34 (2014)

Table 2. NHLS CD4 laboratory statistics for Phase 1 of the cryptococcal screening programme*

Laboratory Statistics	Number
Number of NHLS CD4 laboratories enrolled in screening programme	2
Number of NHLS CD4 laboratories reporting data	2
Number of CrAg screening tests performed	22941
Number of CrAg-positive tests/ number of specimens tested (%)	962/22941 (4.2%)

*Data source: NHLS Corporate Data Warehouse and NHLS laboratory information system

Table 3. Case statistics for Phase 1 of the cryptococcal screening programme*

Case Statistics	Sep-Dec 2012	Jan-Apr 2013	May-Aug 2013	Sep-Dec 2013	Jan-Apr 2014	May-Aug 2014	Total
Number of patients tested for CrAg*	1889	2210	3612	3412	5244	2177	18544
Number of CrAg-positive patients/ number of patients tested for CrAg (%)*	91/1889 (4.8%)	118/2210 (5.3%)	209/3612 (5.8%)	208/3412 (6.1%)	165/5244 (3.1%)	48/2177 (2.2%)	839 [#] /18544 (4.5%)
Number of CrAg-positive patients at enhanced M&E sites	91	117	166	156	108	33	671
Number of CrAg-positive patients known to have had a lumbar puncture**	15	10	22	16	12	8	83
Number of CrAg-positive patients known to have had a lumbar puncture with CM†	9	8	15	14	11	1	58
Number of CrAg-positive patients known to be treated with fluconazole‡	60	65	82	75	55	22	359

*Data source: NHLS Corporate Data Warehouse, NHLS laboratory information system and NICD; where specimen date was unknown, tested date was used as the reference date. Data may be lower than previously reported as patients' previous CrAg negative results are excluded from reporting if they test CrAg positive when screened at a later stage; †data may be incomplete at the time of reporting due to retrospective collection of clinical data; **lumbar puncture is indicated based on clinical findings; CrAg: cryptococcal antigenaemia; CM: cryptococcal meningitis; ‡ Number of CrAg positive patients (839) differs from CrAg positive patients in Table 4 and Table 5 (853) as some cases do not have specimen or tested dates.

Table 4. Number of CrAg-positive patients, by facility, at 21 facilities that refer specimens to the NHLS CD4 laboratory at Charlotte Maxeke Johannesburg Academic Hospital, n=377*

[†]May include hospitalised patients who were not screened through this programme

*Data source: GERMS-SA surveillance programme (data may be incomplete because surveillance audits have not been performed)

Laboratory-Based Nosocomial Disease Surveillance

Reporting period 01/09/2012 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

Staphylococcus aureus (SA) is seen as a common pathogen associated with a wide range of clinical infections (blood stream, lower respiratory tract, skin and soft tissue infections, ventilator-associated pneumonia and central venous catheter associated with blood stream infections and foreign body infections).

The epidemiology of SA is changing. It is one of the most significant pathogens responsible for causing both nosocomial- and community-associated infections, particularly MRSA, which has a high prevalence worldwide as well as a high morbidity and mortality rate. Previously, MRSA was considered a nosocomial pathogen; now it is recovered from patients at admission to hospitals. This community-associated MRSA (CA-MRSA) occurs either from patients that have never been exposed to healthcare settings or patients that have been exposed to recent hospital admissions or any interventions in health care settings.

SA enhanced surveillance from patients with bacteraemia was introduced in September 2012 at three sentinel sites in Gauteng Province: Charlotte Maxeke Johannesburg Academic Hospital, Helen Joseph/Rahima Moosa Mother and Child Hospital, and Steve Biko Pretoria Academic Hospital. From January 2014, surveillance was introduced at two sentinel sites in Western Cape Province: Groote Schuur Hospital and Tygerberg Hospital. We report basic demographic findings from September 2012 to December 2014.

Comments:

- For the period 1 September 2012 to 31 December 2014, 1228 *S. aureus* cases were reported.
- The majority of *S. aureus* cases were 0-9 years of age (35%) and 30-39 years of age (16%).
- The highest case-fatality rate occurred in the ≥ 60 year age group, with more than half of patients dying (56%).
- Antibiotic susceptibility varied by site.
- Thirty-two percent of *S. aureus* isolates were methicillin-resistant.

Laboratory-Based Nosocomial Disease Surveillance - ESKAPE

Reporting period 01/01/2014 to 30/11/2014

Results until end of epidemiologic week 48 (2014)

Programme Description:

The Centre for Opportunistic, Tropical and Hospital Infections is involved in antimicrobial resistance surveillance amongst hospital-associated infections utilising various sources. The source of data for this report is from the NHLS corporate data warehouse (CDW). Blood culture results from *Enterococcus*, *Staphylococcus*, *Klebsiella*, *Acinetobacter*, *Pseudomonas* and ESBL (*Enterobacter* and *E. coli*) (ESKAPE) organisms were cleaned and analysed. These are common, nosocomial, bacterial pathogens that are highly antibiotic-resistant. The data used were from the following hospitals: Charlotte Maxeke Johannesburg Academic Hospital, Chris Hani Baragwanath Hospital, Dr George Mukhari Hospital, Grey's Hospital, Groote Schuur Hospital, Helen Joseph Hospital, Inkosi Albert Luthuli Central Hospital, King Edward VIII Hospital, Mahatma Gandhi Hospital, Nelson Mandela Academic Hospital, RK Khan Hospital, Steve Biko Academic Hospital and Tygerberg Hospital. Cleaning of the data involved creating unique patient identifiers, which enabled us to de-duplicate and produce patient-level data. There was a lack of standardisation across NHLS laboratories on how data was captured. Extensive recoding of antibiotic names, organism names and susceptibility results were required to clean the data and to minimise errors. Six monthly reports will be generated to reflect overall antimicrobial susceptibility patterns per organism and trend of resistance. Due to limited space, hospital-level antibiotic susceptibility data are not included in this report but are available if required.

Comments:

For the 11-month reporting period we reported the most common organisms and their antimicrobial susceptibility; amongst them *K. pneumoniae* was the commonest organism (total of 2369 cases) followed by *S. aureus* (total of 2154 cases).

S. aureus was resistant to oxacillin in 722 (33%) of 2178 isolates. Amongst all isolates, 0.4% was recorded as non-susceptible to vancomycin (no confirmation) and to linezolid, respectively.

Susceptibility testing showed 98% of *E. faecalis* and 96% of *E. faecium* cases were susceptible to vancomycin.

P. aeruginosa showed susceptibility to piperacillin-tazobactam (65%) and high susceptibility to colistin (98%).

K. pneumoniae cases revealed a high rate of ESBL (69%) and retained susceptibility to carbapenems, except 5% consumed non-susceptibility for ertapenem.

Acinetobacter baumannii isolates were highly resistant to most of the antimicrobial agents tested and indicated 5% resistance to colistin.

We would like to acknowledge the CDW team for cleaning the data and preparing the tables and figures.

Laboratory-Based Nosocomial Disease Surveillance - ESKAPE

ESKAPE surveillance

Reporting period 01/01/2014 to 30/11/2014

Results until end of epidemiologic week 48 (2014)

Figure 17 cont. Antimicrobial susceptibility of Gram-negative ESKAPE organisms

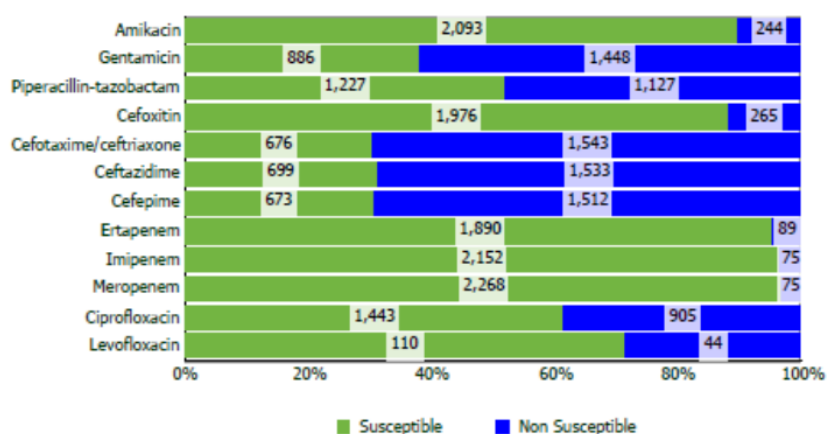

Antimicrobial Susceptibility of *Pseudomonas Aeruginosa*

from 1/1/2014 12:00:01 AM to 11/30/2014

Antimicrobial Susceptibility of *Klebsiella Pneumonia*

from 1/1/2014 12:00:01 AM to 11/30/2014

Antimicrobial Susceptibility of *Escherichia Coli*

from 1/1/2014 12:00:01 AM to 11/30/2014

Antimicrobial Susceptibility of *Enterobacter Cloacae*

from 1/1/2014 12:00:01 AM to 11/30/2014

Due to the lack of standardisation of capturing data at NHLS laboratories across the country, errors might have occurred. However, we have cleaned the data to minimise these errors.

Syndromic Respiratory Disease Surveillance

Reporting period 01/06/2012 to 31/08/2014

Results until end of epidemiologic week 35 (2014)

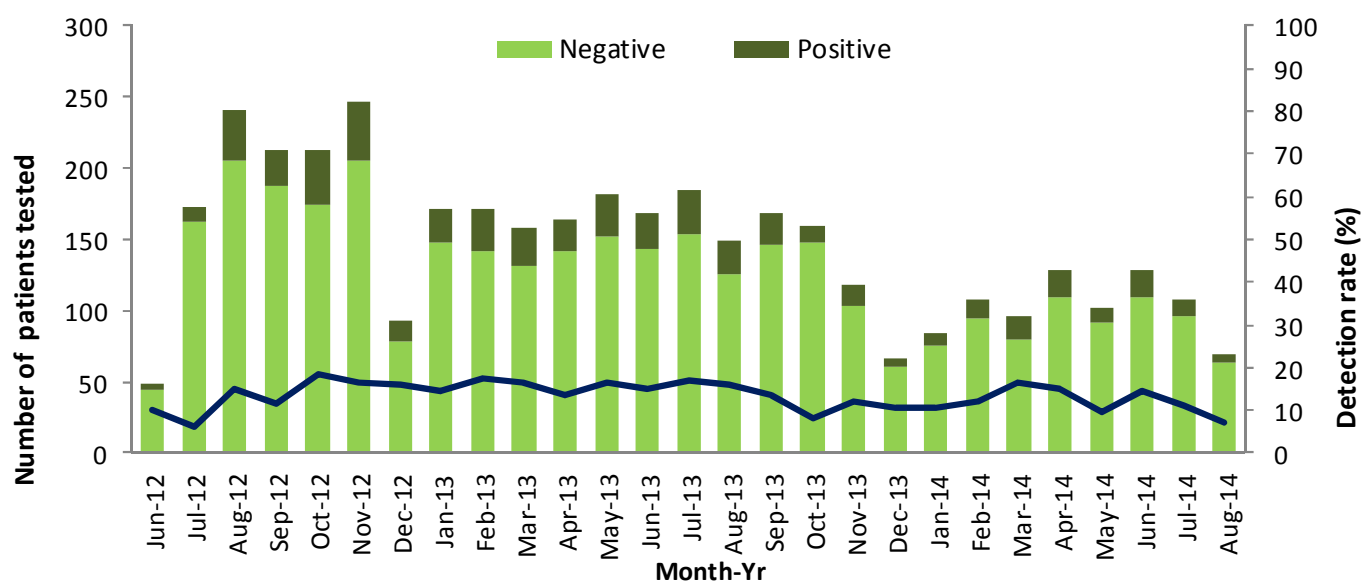

Programme Description:

The data source for this report is the Severe Acute Respiratory Illness (SARI) surveillance programme. SARI is a prospective sentinel hospital-based surveillance system. *Pneumocystis jirovecii* surveillance was conducted at 3 sites: Edendale, Klerksdorp and Tshepong Hospitals. Respiratory tract samples of 3 types (induced sputum (<5 and ≥5 year olds), oral rinses, and nasopharyngeal swabs (only in ≥5 year olds)) were obtained from cases that met the severe respiratory infection case definition. A quantitative real-time PCR was used to test for *P. jirovecii*.

Comments:

During the reporting period, 7649 specimens from 3917 patients were tested for *P. jirovecii*. The overall detection rate was 14% (545/3918). The detection rate is between 7-18%; the detection rate observed in August 2014 may be due to delayed data reporting. Nasopharyngeal specimens accounted for almost half of all specimens taken (3565/7649, 47%). More than one-third of *P. jirovecii* cases were 0-9 years old (1421/3909, 37%). HIV-uninfected individuals with *P. jirovecii* were more common at the extremes of age, whereas HIV-infected individuals with *P. jirovecii* were mostly between the ages of 20-49 years.

Figure 18. Number of specimens tested for *Pneumocystis jirovecii* and detection rate by month from June 2012 to August 2014 (n=3917)

Syndromic Respiratory Disease Surveillance

Laboratory-Based Respiratory and Meningeal Disease Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

The Centre for Respiratory Diseases and Meningitis (CRDM) at the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) monitors invasive disease caused by *Neisseria meningitidis*, *Haemophilus influenzae*, and *Streptococcus pneumoniae* through a national, active, laboratory-based surveillance system (as part of GERMS-SA). All microbiology diagnostic laboratories throughout South Africa are requested to report laboratory-confirmed disease (defined as the isolation of *Neisseria meningitidis*, *Haemophilus influenzae*, or *Streptococcus pneumoniae* from normally sterile site specimens e.g. CSF or blood, or for culture-negative cases, any two of the following: a positive antigen latex agglutination test, a consistent Gram stain, and/or positive polymerase chain reaction [PCR]). Reporting laboratories should include all private- and public-sector health care laboratories, and other specialist laboratories e.g. laboratories serving mining or military hospitals. Available isolates are sent to CRDM for confirmation and further characterisation, including serogrouping. Increasingly more culture-negative specimens are being sent for PCR testing.

Some of the limitations of this surveillance system are that we include only individuals that arrive at hospitals and have specimens taken, and cases are only counted if laboratories report them to us. Quarterly audits to verify completeness of reporting are conducted for all public-sector laboratories. Frequent communications and visits are conducted to improve case reporting. Isolates for serogrouping are not available for cases identified by audit.

Comments:

The meningococcal season has ended. By week 52 in 2014, 188 meningococcal cases had been reported to the NICD. Serogrouping results to date include 39 B, 18 C, 55 W, 1 X and 28 Y. Most of the cases occurred in children aged <10 years. For the same period last year, a total of 233 cases had been reported. An increase in the number of meningococcal cases is usually identified in the winter and spring seasons, with numbers expected to peak during the months of August to October and to decrease in the summer. There has been an overall decrease in reported meningococcal numbers from 2013 to 2014 with a 43% reduction in the W serogroup contributing the most numbers; serogroup B numbers were reduced by 17%.

Two hundred and eighty eight cases of *H. influenzae* have been reported to date in 2014. Serotypes identified to date include 16 a, 49 b, 2 c, 4 d, 3 e, 8 f and 102 non-typeable. Most cases occur in individuals aged <10 years. For the same period last year, a total of 332 cases had been reported.

To date this year, 2539 pneumococcal cases have been reported, compared to 2866 cases reported for the same period last year. Most cases occur in children aged <5 years and adults aged 30-34 years.

Reductions of cases reported in 2014 may reflect the inherent delays of laboratory-based reporting, but may also reflect ongoing operational changes.

* Previously known as serogroup W135. For a comprehensive description of all current *N. meningitidis* serogroups and nomenclature, please refer to the following article: Harrison OB, Claus H, Jiang Y *et al.* Description and nomenclature of *Neisseria meningitidis* capsule locus. Emerg Infect Dis (Internet). 2013 April. Free online access at: http://wwwnc.cdc.gov/eid/article/19/4/11-1799_article.htm

Syndromic Respiratory Disease Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

The data presented in this report are generated from influenza surveillance programmes: the Influenza-like illness (ILI) at primary health clinics and Viral Watch (VW) sites, Severe Acute Respiratory Illness (SARI) and the respiratory consultations and hospitalisations surveillance system.

ILI surveillance at primary health care clinics was started in 2012 at 2 clinics in two provinces, 4 additional clinics were added in 2013.

The Viral Watch (VW) is a sentinel influenza surveillance programme started in 1984 in Gauteng and expanded from 2005 onward to include all 9 provinces in South Africa. The majority (90%) of the sentinel sites are general practitioners. Respiratory specimens (throat, nasal swabs or nasopharyngeal aspirates) are collected from patients of all ages meeting the ILI case definition, which is an acute respiratory illness with a measured temperature of $\geq 38^{\circ}\text{C}$ and cough, with onset within the past 7 days prior to consultation.

The Severe Acute Respiratory Illness (SARI) surveillance program is a prospective sentinel hospital-based surveillance program. It was established in 2009 and is currently conducted at 5 sentinel sites (public hospitals) in 4 provinces of South Africa. Hospitalised patients meeting the surveillance case definition of acute respiratory illness are prospectively enrolled. Clinical and epidemiologic data are collected using standardised questionnaires. Information on in-hospital management and outcome is collected. Upper respiratory tract samples (oropharyngeal and nasopharyngeal swabs in cases ≥ 5 years old or nasopharyngeal aspirate in cases < 5 years of age) are tested for the presence of influenza and other respiratory viruses using RT-PCR.

The respiratory consultations and hospitalisations surveillance system collects anonymous influenza- and pneumonia-associated outpatient consultations and hospitalisations data from one private hospital group in 7 provinces (Gauteng, North West, Free State, Mpumalanga, Eastern and Western Cape and KwaZulu-Natal). These data on the number of consultations and hospitalisations are compared to the influenza season as described by the viral watch and SARI programmes.

Comments:

The 2014 influenza season has ended. The season started in week 21 (week ending 25 May) when the detection rate of VW specimens tested at the NICD rose above 10% and remained there. The season peaked in week 27 (week ending 6 July) and ended in week 37 (week ending 14 September).

ILI programme: In weeks 1 – 48 of 2014, 2293 specimens were received from ILI sites. Influenza A untyped was detected in three patients, A(H1N1)pdm09 in 18, A(H3N2) in 220, and influenza B in 50 patients.

VW programme: During the same period, 1054 specimens were received from VW sites. Influenza A(H1N1)pdm09 was detected in 64 patients, A(H3N2) in 351, and influenza B in 101 patients.

SARI programme: In this time period, 1935 patients with SARI were tested at the 5 sentinel sites. Influenza A(H1N1)pdm09 was detected in three patients, A(H3N2) in 47, and influenza B in 25 patients. In addition 1187 other respiratory viruses were detected in the specimens of 867 patients, rhinovirus (483) accounted for the majority followed by RSV (207) and adenovirus (171).

There are a number of specimens collected during week 52 awaiting results.

Please note that these data are from sentinel sites and reflect trends in the areas with participating sites. Numbers reported reflect numbers of patients enrolled into the surveillance programmes and do not reflect total numbers of patients in the community.

Number of consultations/specimens are reported /analysed by date of consultation. Patients known to have acquired influenza abroad are not included in the tables or epidemiological curves. Source: SARI surveillance, Viral Watch surveillance and Hospital Consultations Netcare

Suspected Measles Case-Based Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

The case-based measles surveillance programme with laboratory support started in 1998 as part of the National Department of Health's measles elimination strategy. Blood and urine or throat/nasopharyngeal swab specimens from suspected measles cases (patients with fever $\geq 38^{\circ}\text{C}$ and rash, and at least one of: cough, coryza or conjunctivitis) nationally are submitted to the NICD for laboratory confirmation. The numbers presented here represent specimens received by the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) and may differ from those presented by the National Department of Health as they may receive information on cases where no specimens were taken.

Comments:

For the period 01 January to 31 December 2014 (week 52), 72 suspected wild-type measles cases were detected from 5,887 suspected measles cases tested from the measles surveillance with date of onset in 2014. The 72 measles cases detected were from Gauteng (23), KwaZulu Natal (6), Northern Cape (30), Western Cape (5), Mpumalanga (3), Free State (2), Eastern Cape (2) and North West (1) provinces.

Laboratory confirmed measles IgM positive cases have shown an increase from week 39 (last week of September) to the end of week 52 nationally. The increase has been in Ekurhuleni district, Gauteng province and in ZF Mgcawu district, Northern Cape province, where a measles outbreak is ongoing. ZF Mgcawu district had reported 28 measles cases by the end of week 52. The measles outbreak in ZF Mgcawu district has affected mostly children aged <9 months, which are yet to receive their first measles vaccine dose, and adults. The increase in measles cases in Ekurhuleni district is mainly in children aged <9 months.

Polio/ Acute Flaccid Paralysis (AFP) Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)

Programme Description:

Data presented in this report are generated from the AFP surveillance database and represent specimens received by the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) and may differ from those presented by the National Department of Health, as they may receive information on cases where no specimens were taken. Every patient with AFP, including Guillain-Barre syndrome, in children younger than 15 years of age, or a patient of any age with a clinical diagnosis of polio made by a medical doctor, must be regarded as a possible polio case until proven otherwise. To meet sample adequacy requirements, all cases require two stool specimens of good condition and sufficient quantity collected at least 24-48 hours apart within 14 days of onset of paralysis.

Comments:

For the reporting period from January 2014 until 31 December 2014, week 52, 897 specimens were received from AFP surveillance in South Africa and 419 AFP cases were detected for 2014. Of the 419 AFP cases, 399 were <15 years with an annualised Non-Polio AFP detection rate of 2.6 per 100 000: range 2.1 to 3.8 (Fig 39). Sabin strains were detected in four cases: one AFP case was a mixture of Sabin type 1, 2 and 3, one case was a mixture of Sabin type 1 and 2, and two cases were Sabin type 2. The overall AFP surveillance detection rate was 2.6, which is above the target rate of 2 per 100 000 population of the children under the age of 15 years. Although the detection rate is above the required target rate in provinces, there are districts which still have low detection rates or are silent and they need to be supported to reduce the risk of polio infection being missed.

Ninety-eight percent of the specimens were received in good condition, while 60% arrived at the NICD within 3 days of collection. Where results were available, 100% were resulted within 14 days of receipt with a Non-Polio enterovirus isolation of 11% (Table 14).

Polio/ Acute Flaccid Paralysis (AFP) Surveillance

Reporting period 01/01/2014 to 31/12/2014

Results until end of epidemiologic week 52 (2014)
