*This Surveillance Report is published by the National Institute for Communicable Diseases (NICD), a division of the National Health Laboratory Service (NHLS), on a monthly basis to provide information on communicable diseases in South Africa. Much of the information is therefore preliminary and should not be cited or utilised for publication. Questions and comments may be addressed to the Division of Public Health Surveillance and Response and will be referred on to the responsible Centres: pennyc@nicd.ac.za; Private Bag X4, Sandringham, 2131, South Africa*

## Surveillance Summary

- *Salmonella* Typhi has been reported for 45 cases to date in 2014.
- No cases of *Vibrio cholerae* O1 have been reported to date in 2014. For the same period last year, 1 non-invasive case had been reported.
- Fifty-nine specimens have tested positive for rotavirus to date.
- Laboratory-based screening for cryptococcal disease has been operational in the City of Johannesburg Metro for more than 18 months and in the City of Ekurhuleni Metro for just over a year. To date, 16417 patients have been screened at selected facilities; 866 (5.3%) tested positive for cryptococcal antigen (CrAg).
- To 31 May 2014, 736 *S. aureus* cases were reported over an 19 month period. The majority of cases were <10 years old (34%). The proportion of methicillin-resistant isolates were 29%.
- A total of 3408 patients over a 23 month period were tested for *Pneumocystis jirovecii*. Four hundred and eighty-five (14%) cases were positive for *P. jirovecii*. These cases positive for *P. jirovecii* could indicate colonisation or it could be true disease.
- Sporadic cases of meningococcal disease continue to be reported across the country. By week 22 in 2014, 44 meningococcal cases had been reported to the NICD. Serogroups identified to date include 11 B, 9 C, 11 W, 1 X and 5 Y. The most cases occur in children aged <10 years, with a second peak in adults aged 30-39 years.
- By week 22 in 2014, 115 cases of *H. influenzae* had been reported. Serotypes identified to date include 4 a, 20 b, 1 f and 36 non-typeable. Most cases occur in individuals aged <10 years.
- The number of pneumococcal cases was lower than that reported last year (839 versus 963). Most cases occur in children aged <5 years and adults aged 30-34 years.
- To date in 2014, 50 influenza isolates have been detected. Thirty-seven of the isolates were detected through Viral Watch, 4 through SARI and 9 through the influenza-like illness programme.
- Five measles cases were detected; 2 adult measles cases in Gauteng province (Johannesburg Metropolitan district) and 1 measles case each from Mpumalanga province, KwaZulu-Natal province (Umgungundlovu district) and Western Cape province (City Of Cape Town). Two of the children were <5 years and had received a single dose of measles vaccine, whereas 1 child was between 5-14 years.
- 159 AFP cases <15 years of age have been reported to date with an annualized non-polio AFP detection rate of 2.5 per 100,000 population.

# Laboratory-Based Enteric Disease Surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

## Programme Description:

The Centre for Enteric Diseases (CED) at the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) monitors disease caused by *Salmonella* Typhi and *Vibrio cholerae* through a national, active, laboratory-based surveillance system (as part of GERMS-SA). All microbiology diagnostic laboratories throughout South Africa are requested to report laboratory-confirmed disease (defined as the isolation of *Salmonella* Typhi and *Vibrio cholerae* from any specimen. Reporting laboratories should include all private- and public-sector health care laboratories, and other specialist laboratories e.g. laboratories serving mining or military hospitals. Available isolates are sent to CED for confirmation and further characterisation, including serotyping.

Some of the limitations of this surveillance system are that we include only individuals that arrive at hospitals and have specimens taken, and cases are only counted if laboratories report them to us. Quarterly audits to verify completeness of reporting are conducted for all public-sector laboratories. Frequent communications and visits are conducted to improve case reporting. Isolates for serotyping are not available for cases identified by audit.

## Comments:

By week 22 in 2014, *Salmonella* Typhi had been reported for 45 cases (35 invasive), in Eastern Cape, Gauteng, KwaZulu Natal, Mpumalanga and Western Cape provinces. For the same period last year, 35 cases of *Salmonella* Typhi had been reported.

No cases of *Vibrio cholerae* O1 have been reported to date in 2014. For the same period last year, 1 case had been reported - non-invasive, serotype Inaba.

## Laboratory-Based Enteric Disease Surveillance

### *Vibrio cholerae* O1 surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

**Figure 4. Number of *Vibrio cholerae* O1 cases by month in South Africa, 2013 and 2014**

**Figure 5. Number of *Vibrio cholerae* O1 cases by province in South Africa, 2013 and 2014**

**Figure 6. Number of *Vibrio cholerae* O1 cases by age group in South Africa, 2013 and 2014**

# Syndromic Diarrhoeal Disease Surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

## Programme Description:

In April 2009, the National Institute for Communicable Diseases of the National Health Laboratory Service (NICD/NHLS) in Johannesburg implemented a diarrhoea sentinel surveillance programme at five hospitals in four provinces of South Africa (Gauteng, North West, KwaZulu-Natal and Mpumalanga). The aim of the programme is to evaluate the prevalence of rotavirus in diarrhoea cases and to monitor the effect of the introduction of the monovalent Rotarix® vaccine into the expanded programme on immunisation. The rotavirus vaccine was introduced in August 2009.

Children < 5 years admitted (slept overnight in hospital) to one of the sentinel hospitals for acute diarrhoea ( $\geq 3$  loose stools in 24 hour period and onset within 7 days) are eligible for enrolment in the surveillance. Stool specimens are collected and tested for rotavirus at the NICD/NHLS and at the Diarrhoeal Pathogens Research Unit (DPRU), University of Limpopo, Medunsa Campus using the ProSpecT Rotavirus ELISA kit (Oxoid, UK).

## Comments:

The rotavirus season has started - week 16 reported a rotavirus detection rate of 23.8% and week 17 of 23.1%. The numbers in weeks 18 and 19 dropped to below the 20% threshold (7.7% and 11.1%), which may be partially due to lower specimen collection during the holidays. However, the rotavirus detection rate has rebounded to 30% in weeks 20 and 21. In 2013, the rotavirus season started in week 19 (week ending 12 May) and ended in week 40 (week ending 6 October).

For 2014 to date, 59/508 (11.6%) samples tested positive for rotavirus.

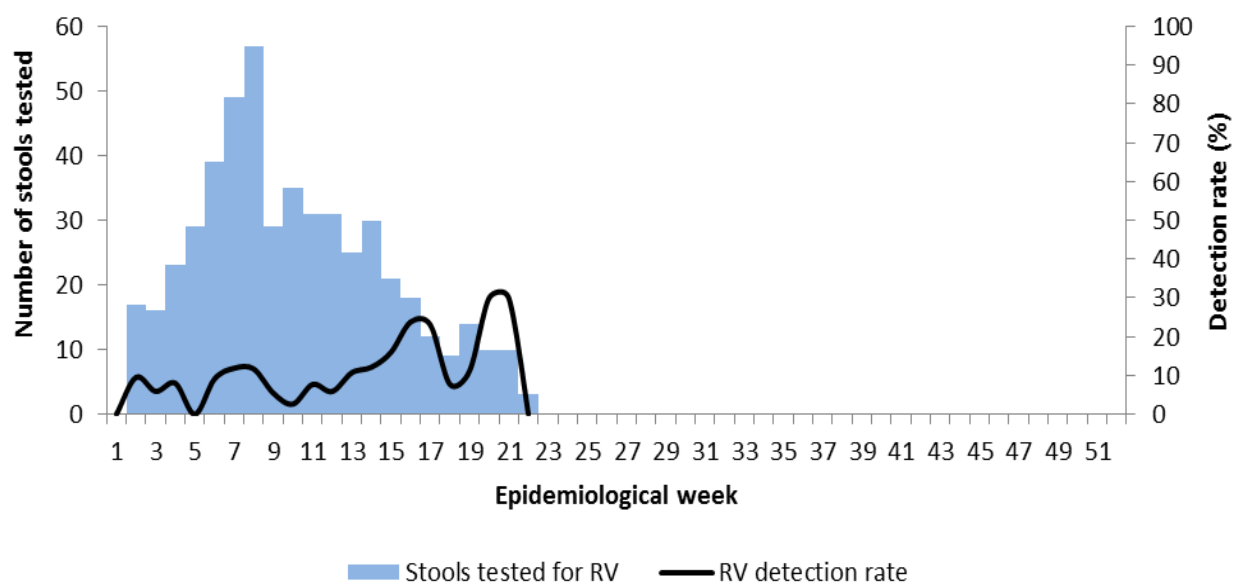

# Syndromic Diarrhoeal Disease Surveillance

## Rotavirus (ROTA) surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

**Figure 7. Number of stools tested for rotavirus and detection by week, 2014**

The rotavirus detection (in percentage) is the number of rotavirus-positive stool tests divided by the number of rotavirus stool tests in acute diarrhoea hospitalisations.

**Table 1. Cumulative number of stools tested rotavirus positive and total number of stools collected by hospital, 2014**

Hospital	Rotavirus Positive	Total stools tested
Chris Hani Baragwanath	10	155
Mapulaneng	2	28
Matikwane	1	46
Dr George Mukhari	1	53
Edendale	5	21
Red Cross Children's	40	205
<b>Total:</b>	<b>59</b>	<b>508</b>

# Sexually Transmitted Disease Surveillance

Reporting period 01/04/2014 to 30/04/2014

Results until end of epidemiologic week 18 (2014)

## Programme Description:

The Gauteng clinical STI sentinel surveillance programme was introduced in 1997 by the Sexually Transmitted Infections Reference Centre (Centre for HIV and STI, National Institute for Communicable Diseases) in partnership with the Gauteng Department of Health. The aim of the surveillance program is to monitor STI trends and set up priorities for STI management and provincial control programmes. The data presented below are a summary for the period 1 - 30 April 2014.

## Comments:

For the period up to 30 April 2014, 952 new STI syndrome episodes were reported by sentinel sites.

Females represented 53% (n=500) and males 47% (n=452) of the surveyed population. Amongst males, 72% (323/ 452) of STI syndromes were MUS (Male Urethritis Syndrome) and amongst females, 73% (365/ 500) of STI syndromes were VDS (Vaginal Discharge Syndrome). A total of 1001 partner notification slips were issued to 952 patients with new STI episodes, resulting in an overall partner slip issue rate of 100%.

MUS and VDS continued to be the most common syndromes in this patient population group.

**Figure 8. Percentage distribution of new STI syndrome episodes per surveillance region, 1 - 30 April 2014**

# Laboratory-Based Screening for Cryptococcal Disease (Phase 1: Gauteng)

Reporting period 03/09/2012 to 23/05/2014

Results until end of epidemiologic week 21 (2014)

## Programme Description:

The NICD's Centre for Opportunistic, Tropical and Hospital Infections (COTHI), in collaboration with the Department of Health and several partner organizations, implemented the first phase of laboratory-based screening for cryptococcal disease. The screen-and-treat programme began at 21 health care facilities in the City of Johannesburg in September 2012. In April 2013, 85 facilities in Ekurhuleni were also included. Routine blood samples submitted for a CD4+ T-lymphocyte (CD4) count from patients seen at these 106 facilities are reflexively tested for cryptococcal antigen (CrAg) using a cryptococcal lateral flow assay (LFA) if the CD4 count is less than 100 cells/ $\mu$ l. CrAg test results are included on the CD4 count laboratory report. As part of intensive monitoring and evaluation of the programme, patients with cryptococcal antigenaemia, who provide informed consent, are followed up prospectively for up to 6 months. The following data are collected: lumbar puncture results; antifungal treatment; antiretroviral treatment; time from CrAg testing to treatment initiation; adverse events and outcome (i.e. development of cryptococcal meningitis (CM), death or loss to follow-up). Other key programme indicators such as number of cases of CM detected at the regional hospitals in the screening districts, the number of healthcare workers trained and availability of fluconazole at facilities are collected. The objective of this report is to provide monthly updates of selected programme indicators to all stakeholders. Data in this report are incomplete due to retrospective collection of clinical data.

## Comments:

Up to 31 May 2014, 16417 patients with a CD4 count  $<100$  cells/ $\mu$ l have been screened; 866 (5.3%) tested positive for CrAg. In Johannesburg, 59% (226/383) of patients were detected at Helen Joseph Hospital, and in Ekurhuleni, 12% (60/483) of patients were detected at Tambo Memorial Hospital. Twenty percent (167/845) of CrAg-positive patients with available age data were between the ages of 30 and 44 years. During the reporting period, 241 cases of laboratory-confirmed CM were diagnosed at three regional hospitals (Helen Joseph, Rahima Moosa Mother and Child and South Rand) in Johannesburg and 417 cases of CM were diagnosed at four regional hospitals in Ekurhuleni (Bertha Gxowa, Natalspruit, Pholosong and Tambo Memorial); this number may include hospitalised patients who were not screened through this programme.

# Laboratory-Based Screening for Cryptococcal Disease (Phase 1: Gauteng)

Reporting period 03/09/2012 to 23/05/2014

Results until end of epidemiologic week 21 (2014)

**Table 2. NHLS CD4 laboratory statistics for Phase 1 of the cryptococcal screening programme\***

\*Data source: GERMS-SA surveillance programme (data may be incomplete because surveillance audits have not been performed)

## Laboratory-Based Nosocomial Disease Surveillance

Reporting period 01/09/2012 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

### Programme Description:

*Staphylococcus aureus* (SA) is seen as a common pathogen associated with a wide range of clinical infections (blood stream, lower respiratory tract, skin and soft tissue infections, ventilator-associated pneumonia and central venous catheter associated with blood stream infections and foreign body infections).

The epidemiology of SA is changing. It is one of the most significant pathogens responsible for causing both nosocomial- and community-associated infections, particularly MRSA, which has a high prevalence worldwide as well as a high morbidity and mortality rate. Previously, MRSA was considered a nosocomial pathogen; now it is recovered from patients at admission to hospitals. This community-associated MRSA (CA-MRSA) occurs either from patients that have never been exposed to healthcare settings or patients that have been exposed to recent hospital admissions or any interventions in health care settings.

SA enhanced surveillance from patients with bacteraemia was introduced in September 2012 at three sentinel sites in Gauteng Province: Charlotte Maxeke Johannesburg Academic Hospital, Helen Joseph/Rahima Moosa Mother and Child Hospital, and Steve Biko Pretoria Academic Hospital. From January 2014, surveillance was introduced at two sentinel sites in Western Cape Province: Groote Schuur Hospital and Tygerberg Hospital. We report basic demographic findings from September 2012 to May 2014.

### Comments:

- For the period 1 September 2012 to 31 May 2014, 736 *S. aureus* cases were reported.
- The majority of *S. aureus* cases were 0-9 years of age (34%) and 30-39 years of age (15%).
- The highest case-fatality rate occurred in the  $\geq 60$  year age group, with more than half of patients dying (57%).
- Antibiotic susceptibility varied by site.
- Twenty-nine percent of *S. aureus* isolates were methicillin-resistant.

# Laboratory-Based Nosocomial Disease Surveillance - ESKAPE

Reporting period 01/06/2013 to 31/10/2013

Results until end of epidemiologic week 44 (2013)

## Programme Description:

The Centre for Opportunistic, Tropical and Hospital Infections is involved in hospital-associated infection surveillance utilising various sources. The source of data for this report is from the NHLS corporate data warehouse (CDW). Blood culture results from *Enterococcus*, *Staphylococcus*, *Klebsiella*, *Acinetobacter*, *Pseudomonas* and ESBL (*Enterobacter* and *E. coli*) (ESKAPE) organisms were cleaned and analysed. These are common, nosocomial, bacterial pathogens that are highly antibiotic-resistant. The data used were from the following hospitals: Charlotte Maxeke Johannesburg Academic Hospital, Chris Hani Baragwanath Hospital, Dr George Mukhari Hospital, Grey's Hospital, Groote Schuur Hospital, Helen Joseph Hospital, Inkosi Albert Luthuli Central Hospital, King Edward VIII Hospital, Mahatma Gandhi Hospital, Nelson Mandela Academic Hospital, RK Khan Hospital, Steve Biko Academic Hospital and Tygerberg Hospital. Cleaning of the data involved creating unique patient identifiers, which enabled us to deduplicate and produce patient-level data. There was a lack of standardisation across NHLS laboratories on how data was captured. Extensive recoding of antibiotic names, organism names, and susceptibility results were required to clean the data and to minimise errors. Quarterly reports will be generated to reflect overall antimicrobial susceptibility patterns per organism. Due to limited space, hospital-level antibiotic susceptibility data are not included in this report but are available if required.

## Comments:

For the 5-month reporting period, *S. aureus* was the most common organism reported with 941 cases, 38% of which were MRSA isolates.

100% of *E. faecalis* and 87% of *E. faecium* cases were susceptible to vancomycin.

*P. aeruginosa* showed decreased susceptibility to piperacillin-tazobactam (61%) and high susceptibility to colistin.

*K. pneumoniae* cases showed a high rate of ESBL (76%) and retained susceptibility to carbapenems, except 5% had no susceptible rate for ertapenem.

*Acinetobacter baumannii* isolates were highly resistant to most of the antimicrobial agents tested.

We would like to acknowledge the CDW team for cleaning the data and preparing the tables and figures.

### Antimicrobial Susceptibility of *Pseudomonas aeruginosa* from June to October 2013

### Antimicrobial Susceptibility of *Klebsiella pneumoniae* from June to October 2013

### Antimicrobial Susceptibility of *Escherichia coli* from June to October 2013

### Antimicrobial Susceptibility of *Enterobacter cloacae* complex from June to October 2013

Due to the lack of standardisation of capturing data at NHLS laboratories across the country, errors might have occurred. However, we have cleaned the data to minimise these errors.

# Syndromic Respiratory Disease Surveillance

Reporting period 01/06/2012 to 30/04/2014

Results until end of epidemiologic week 18 (2014)

## Programme Description:

The data source for this report is the Severe Acute Respiratory Illness (SARI) surveillance programme. SARI is a prospective sentinel hospital-based surveillance system. *Pneumocystis jirovecii* surveillance was conducted at 3 sites: Edendale, Klerksdorp and Tshepong Hospitals. Respiratory tract samples of 3 types (induced sputum (<5 and ≥5 year olds), oral rinses, and nasopharyngeal swabs (only in ≥5 year olds)) were obtained from cases that met the severe respiratory infection case definition. A quantitative real-time PCR was used to test for *P. jirovecii*.

## Comments:

During the reporting period, 6674 specimens from 3408 patients were tested for *P. jirovecii*. The overall detection rate was 14% (485/3408). The detection rate is between 6-18%; the detection rate observed in April may be due to delayed data reporting. Nasopharyngeal specimens accounted for almost half of all specimens taken (3174/6674; 48%). More than one-third of *P. jirovecii* cases were 0-9 years old (1228/3408; 36%). HIV-uninfected individuals with *P. jirovecii* were more common at the extremes of age, whereas HIV-infected individuals with *P. jirovecii* were mostly between the ages of 20-49 years.

**Figure 18. Number of specimens tested for *Pneumocystis jirovecii* and detection rate by month from June 2012 to April 2014 (n=3408)**

# Laboratory-Based Respiratory and Meningeal Disease Surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

## Programme Description:

The Centre for Respiratory Diseases and Meningitis (CRDM) at the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) monitors invasive disease caused by *Neisseria meningitidis*, *Haemophilus influenzae*, and *Streptococcus pneumoniae* through a national, active, laboratory-based surveillance system (as part of GERMS-SA). All microbiology diagnostic laboratories throughout South Africa are requested to report laboratory-confirmed disease (defined as the isolation of *Neisseria meningitidis*, *Haemophilus influenzae*, or *Streptococcus pneumoniae* from normally sterile site specimens e.g. CSF or blood, or for culture-negative cases, any two of the following: a positive antigen latex agglutination test, a consistent Gram stain, and/or positive polymerase chain reaction [PCR]). Reporting laboratories should include all private- and public-sector health care laboratories, and other specialist laboratories e.g. laboratories serving mining or military hospitals. Available isolates are sent to CRDM for confirmation and further characterisation, including serogrouping. Increasingly more culture-negative specimens are being sent for PCR testing.

Some of the limitations of this surveillance system are that we include only individuals that arrive at hospitals and have specimens taken, and cases are only counted if laboratories report them to us. Quarterly audits to verify completeness of reporting are conducted for all public-sector laboratories. Frequent communications and visits are conducted to improve case reporting. Isolates for serogrouping are not available for cases identified by audit.

## Comments:

Sporadic cases of meningococcal disease continue to be reported across the country. By week 22 in 2014, 44 meningococcal cases had been reported to the NICD. Serogroups identified to date include 11 B, 9 C, 11 W\*, 1 X and 5 Y. The most cases occur in children aged <10 years, with a second peak in adults aged 30-39 years. For the same period last year, a total of 62 cases had been reported. An increase in the number of meningococcal cases is usually identified in the winter and spring seasons, with numbers expected to peak during the months of August to October and to decrease in the summer.

One hundred and fifteen cases of *H. influenzae* have been reported to date in 2014. Serotypes identified to date include 4 a, 20 b, 1 f and 36 non-typeable. Most cases occur in individuals aged <10 years. For the same period last year, a total of 134 cases had been reported.

To date this year, 839 pneumococcal cases have been reported, compared to 963 cases reported for the same period last year. Most cases occur in children aged <5 years and adults aged 30-34 years.

Reductions of cases reported in 2014 may reflect the inherent delays of laboratory-based reporting, but may also reflect ongoing operational changes.

\* Previously known as serogroup W135. For a comprehensive description of all current *N. meningitidis* serogroups and nomenclature, please refer to the following article: Harrison OB, Claus H, Jiang Y *et al.* Description and nomenclature of *Neisseria meningitidis* capsule locus. Emerg Infect Dis (Internet). 2013 April. Free online access at: [http://wwwnc.cdc.gov/eid/article/19/4/11-1799\\_article.htm](http://wwwnc.cdc.gov/eid/article/19/4/11-1799_article.htm)

# Syndromic Respiratory Disease Surveillance

Reporting period 01/01/2014 to 01/06/2014

Results until end of epidemiologic week 22 (2014)

## Programme Description:

The data presented in this report are generated from influenza surveillance programmes: the Influenza-like illness (ILI) at primary health clinics and Viral Watch (VW) sites, Severe Acute Respiratory Illness (SARI) and the respiratory consultations and hospitalisations surveillance system.

ILI surveillance at primary health care clinics was started in 2012 at 2 clinics in two provinces, 4 additional clinics were added in 2013.

The Viral Watch (VW) is a sentinel influenza surveillance programme started in 1984 in Gauteng and expanded from 2005 onward to include all 9 provinces in South Africa. The majority (90%) of the sentinel sites are general practitioners. Respiratory specimens (throat, nasal swabs or nasopharyngeal aspirates) are collected from patients of all ages meeting the ILI case definition, which is an acute respiratory illness with a measured temperature of  $\geq 38^{\circ}\text{C}$  and cough, with onset within the past 7 days prior to consultation.

The Severe Acute Respiratory Illness (SARI) surveillance program is a prospective sentinel hospital-based surveillance program. It was established in 2009 and is currently conducted at 5 sentinel sites (public hospitals) in 4 provinces of South Africa. Hospitalised patients meeting the surveillance case definition of acute respiratory illness are prospectively enrolled. Clinical and epidemiologic data are collected using standardised questionnaires. Information on in-hospital management and outcome is collected. Upper respiratory tract samples (oropharyngeal and nasopharyngeal swabs in cases  $\geq 5$  years old or nasopharyngeal aspirate in cases  $< 5$  years of age) are tested for the presence of influenza and other respiratory viruses using RT-PCR.

The respiratory consultations and hospitalisations surveillance system collects anonymous influenza- and pneumonia-associated outpatient consultations and hospitalisations data from one private hospital group in 7 provinces (Gauteng, North West, Free State, Mpumalanga, Eastern and Western Cape and KwaZulu-Natal). These data on the number of consultations and hospitalisations are compared to the influenza season as described by the viral watch and SARI programmes.

## Comments:

The 2014 influenza season has not yet started. The influenza season is considered to have started when the detection rate of VW specimens tested at the NICD has risen above 10% and remains there for  $\geq 2$  weeks. Although the detection rate has risen above 10% during several weeks, it has not remained there. However, the number of specimens submitted by VW sites has increased from an average of 35 per month during March and April to 104 for the month of May.

ILI programme: In the first 22 weeks of 2014, 511 specimens were received from ILI sites. Influenza A(H1N1)pdm09 was detected in two, A(H3N2) in four, and influenza B in three specimens.

VW programme: During the same period, 199 specimens were received from VW sites. Influenza A(H1N1)pdm09 was detected in 12 patients, influenza A(H3N2) in 20 patients, and influenza B in five patients. The majority 25/37 (68%) of influenza detections were from patients in the WCP.

SARI programme: In this time period, 679 patients with SARI were tested at the 4 sentinel sites. Influenza A untyped as yet and influenza A(H1N1)pdm09 were detected in one patient each, and influenza A(H3N2) in two patients. In addition 498 other respiratory viruses were detected in the specimens of 386 patients, rhinovirus (197) accounted for the majority followed by RSV (185) and adenovirus (56).

There are a number of specimens collected during week 22 awaiting results.

Please note that these data are from sentinel sites and reflect trends in the areas with participating sites. Numbers reported reflect numbers of patients enrolled into the surveillance programmes and do not reflect total numbers of patients in the community.

Number of consultations/specimens are reported /analysed by date of consultation. Patients known to have acquired influenza abroad are not included in the tables or epidemiological curves. Source: SARI surveillance, Viral Watch surveillance and Hospital Consultations Netcare

## Suspected Measles Case-Based Surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

### Programme Description:

The case-based measles surveillance programme with laboratory support started in 1998 as part of the National Department of Health's measles elimination strategy. Blood and urine or throat/nasopharyngeal swab specimens from suspected measles cases (patients with fever  $\geq 38^{\circ}\text{C}$  and rash, and at least one of: cough, coryza or conjunctivitis) nationally are submitted to the NICD for laboratory confirmation. The numbers presented here represent specimens received by the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) and may differ from those presented by the National Department of Health as they may receive information on cases where no specimens were taken.

### Comments:

For the period 01 January to 31 May 2014 (week 22), 5 suspected wild-type measles cases were detected from 1476 suspected measles cases tested from the measles surveillance with date of onset in 2014. The 5 measles cases detected were from Gauteng (2), Mpumalanga (1), KwaZulu Natal (1) and Western Cape provinces (1).

## Polio/ Acute Flaccid Paralysis (AFP) Surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

### Programme Description:

Data presented in this report are generated from the AFP surveillance database and represent specimens received by the National Institute for Communicable Diseases (NICD) of the National Health Laboratory Service (NHLS) and may differ from those presented by the National Department of Health, as they may receive information on cases where no specimens were taken. Every patient with AFP, including Guillain-Barre syndrome, in children younger than 15 years of age, or a patient of any age with a clinical diagnosis of polio made by a medical doctor, must be regarded as a possible polio case until proven otherwise. To meet sample adequacy requirements, all cases require two stool specimens of good condition and sufficient quantity collected at least 24-48 hours apart within 14 days of onset of paralysis.

### Comments:

For the reporting period from January 2014 until 31 May 2014 week 22, 331 specimens were received from AFP surveillance in South Africa and 159 AFP cases were detected for 2014. Of the 167 AFP cases, 159 were <15 years with an annualised Non-Polio AFP detection rate of 2.5 per 100 000: range 1.4 to 4.3 (Fig 37). Sabin strains were detected in two cases: one AFP case was Sabin type 1, 2 and 3 whereas the other one was Sabin type. The overall AFP surveillance detection rate was 2.5, which is above the target rate of 2 per 100 000 population of the children under the age of 15 years. Although the detection rate is above the required target rate in province, there are districts which still have low detection rates or are silent and they need to be supported to reduce the risk of polio infection being missed.

Ninety-seven percent of the specimens were received in good condition, while 69% arrived at the NICD within 3 days of collection. Where results were available, 100% were resulted within 14 days of receipt with a Non-Polio enterovirus isolation of 11% (Table 13).

## Polio/ Acute Flaccid Paralysis (AFP) Surveillance

Reporting period 01/01/2014 to 31/05/2014

Results until end of epidemiologic week 22 (2014)

**Figure 37. Annualised Non-Polio AFP detection rate by province, South Africa, 2014**

\*Target for detection rate is 2/100,000 population

**Table 13. Acute Flaccid Paralysis (AFP) surveillance, laboratory performance indicators, South Africa, 2014\***

Laboratory indicators	2014*	Target
Specimens received in good condition	97%	90%
Specimens received within 3 days of collection	69%	80%
Specimens resulted within 14 days of receipt	100%	80%
Non-Polio enterovirus isolation rate	11%	10%

\* Samples received in 2014 (1 January - 31 May)
